2

House Keeping Problems

- ✧ What is wrong with the following code?

```
class Array {  
public:  
    void initArray(int arraySize);  
    void insertElement(int element, int slot);  
    int getElement(int slot) const;  
    void cleanUp();  
private:  
    int m_arraySize;  
    int *m_arrayData;  
};  
void Array::initArray(int arraySize) {  
    m_arrayData = new int[arraySize];  
    m_arraySize = arraySize;  
}  
void main() {  
    Array array;  
    array.insertElement(10, 0);  
}
```

**Assume insertElement(), getElement(),
and cleanUp() are defined elsewhere.**

In the client code: main
1. Forget to initialize the object array
(there is no call to initArray())
2. Forget to call cleanUp() code segment

3

Invalid Internal State

- ✧ Initialization
 - ★ Interface functions are required to maintain the internal state of an object such that they are valid and consistent all the time.
 - ★ Without suitable initialization, the object's initial state would be invalid.
 - ★ We need a method to guarantee that each new object is well initialized. No additional care should be taken by a user.
- ✧ Clean up
 - ★ Clean up is important if a program is supposed to run for a long time. If resources (memory, file, ...) are occupied one by one and forget to released afterwards, sooner or later no program would have enough resources to get executed.
 - ★ We need a method to guarantee that each object is well cleaned up. No additional care should be taken by a user.

4

Constructors

- ✧ **ctor:** A **constructor** is a function executed automatically when an object comes into existence.
- ✧ Syntax
 - * The name of the constructor is the same as the class name
 - * Must **not** have a return type
 - * Parameters must be supplied when the object is defined.
 - * Do **not** call it (explicitly) inside the program except the following 3 situations:
 1. new statements, 2. initialization lists, 3. temporary objects

<pre>class Array { public: Array(int arraySize); void insertElement(int element, int slot); int getElement(int slot) const; private: int m_arraySize; int *m_array; };</pre>	<pre>void main() { Array array(20); array.insertElement(10, 0); } Array::Array(int arraySize) { m_array = new int[arraySize]; m_arraySize = arraySize; }</pre>
---	---

Destructors

- ✧ **dtor:** A **destructor** is a function executed automatically when an object's life comes to an end. (goes out of scope, program ends, or is deleted dynamically)
- ✧ Syntax
 - * The name of the destructor must be the same as the name of the class preceded by ~ (tilde).
 - ~Array();
 - * Destructors take **no** arguments and return **no** values
- ✧ **Purpose:** to free any resource (memory, file, network) allocated by the object.

<pre>class Array { public: ... ~Array(); ... };</pre>	<pre>Array::~~Array() { delete [] m_array; }</pre>
---	--

6

When are ctors and dtors invoked?

- ✧ Static variables (local, global)

```
void Foo() {
    Array array(20); // ctor invoked
    array.insertElement(10, 0);
    cout << array.getElement(0);
} // dtor invoked
```

codes inserted by the C++ compiler

What would happen if there were no destructor?

- * dtor of a global variable will be invoked when the program exits

- ✧ Dynamic variables

```
Array *Foo(int numElements) {
    Array *array;
    array = new Array(numElements); // ctor invoked
    return array;
}

void Bar() {
    Array *mainData = Foo(20);
    delete mainData; // dtor invoked
}
```

What would happen if we did not call delete?

7

Advantages Achieved by OOP

Automatic initialization

```
Array::Array(int arraySize) {
    m_array = new int[arraySize];
    m_arraySize = arraySize;
}
```

Reduced memory-leakage risks

```
Array::~~Array(){
    delete [] m_array;
}
```

Safe client/server programming

```
void Array::insertElement(int element, int slot) {
    if ((slot < m_arraySize) && (slot >=0))
        m_array[slot] = element;
    else
        cout << "Warning, out of range!!!";
}

int Array::getElement(int slot) const {
    if ((slot < m_arraySize) && (slot >= 0))
        return m_array[slot];
    else {
        cout << "Warning, out of range!!!";
        return 0;
    }
}
```

Better abstraction

```
cout << array.getElement(0);
```

Conceptually, an array is no longer just a chunk of data storages.

8

Multiple Constructors

- ✧ A class can have more than one constructor (function overloading)

```
class Name
{
public:
    Name();
    Name(char *firstName, char *lastName);
    ~Name();
    void setName(char *firstName, char *lastName);
    void printName() const;
private:
    char *m_firstName;
    char *m_lastName;
};

Name::Name()  <----- This ctor has special name:
{
    m_firstName = 0;
    m_lastName = 0;
}
“default constructor”.

Name::Name(char *firstName, char *lastName)
{
    setName(firstName, lastName);
}
```

9

Multiple Constructors (cont'd)

```
void Name::setName(char *firstName, char *lastName)
{
    m_firstName = new char[strlen(firstName)+1];
    m_lastName = new char[strlen(lastName)+1];
    strcpy(m_firstName, firstName);
    strcpy(m_lastName, lastName);
}

Name::~Name()                void Name::printName() const
{
    delete[] m_firstName;     {
    delete[] m_lastName;      if (m_firstName) cout << m_firstName << ' ';
                             if (m_lastName) cout << m_lastName << ' ';
}                             }
```

- Usage:

```
void main()
{
    Name name1, name2("Mary", "Smith");
    name1.setName("Mark", "Anderson");
    name1.printName(); name2.printName();
}
```

10

Constructors and Arrays

- ✧ If you try to define an array of objects, you can NOT do this

```
class Name
{
public:
    Name(char *firstName, char *lastName);
    ~Name();
    void setName(char *firstName, char *lastName);
    void printName() const;
private:
    char *m_firstName;
    char *m_lastName;
};

void main()
{
    Name names[100];
    names[0].setName("Mark", "Anderson");
    names[0].printName();
}
```

- error C2512: 'Name' : no appropriate default constructor available

Name() is the so-called default constructor

```
Name names[] = {Name("Mark", "Anderson"), name1};
```

11

Solutions to Array of Objects

- ✧ Solution 1: provide a ctor without arguments ... i.e. the default ctor

```
class Name {
public:
    Name();
    Name(char *firstName, char *lastName);
    ~Name();
    void setName(char *firstName, char *lastName);
    void printName() const;
private:
    char *m_firstName;
    char *m_lastName;
};
```

- ✧ Solution 2: have no ctor at all ... i.e. use the implicit default ctor

```
class Name {
public:
    ~Name();
    void setName(char *firstName, char *lastName);
    void printName() const;
private:
    char *m_firstName;
    char *m_lastName;
};
```

12

Constructors with Default Arguments

- Consider this class with two constructors

```
class Account {
public:
    Account();
    Account(double startingBalance);
    void changeBalance(double amount);
    void showBalance() const;
private:
    double m_balance;
};

Account::Account() {
    m_balance = 0.0;
}

Account::Account(double startingBalance) {
    m_balance = startingBalance;
}
```

```
void main() {
    Account client1, client2(100.0);
    client1.showBalance();
    client2.showBalance();
}
```

Output:
0.0
100.0

13

Ctor with Default Arguments (cont'd)

- The class is rewritten as follows

```
class Account {
public:
    Account(double startingBalance=0.0);
    void changeBalance(double amount);
    void showBalance() const;
private:
    double m_balance;
};

Account::Account(double startingBalance) {
    m_balance = startingBalance;
}
```

The single ctor is exactly the same as before

- We can now declare an array of Account.

```
void main() {
    Account clients[100];
    clients[0].changeBalance(100.0); clients[0].showBalance();
}
```

This works fine without default ctor.

14

Initialization Lists

- Consider the following class

```
enum Breed {undefined, collie, poodle, coca, bulldog};
class Dog {
public:
    Dog();
    Dog(char *name, Breed breed, int age);
    ~Dog();
    void list() const;
private:
    char *m_name;
    Breed m_breed;
    int m_age;
};
```

★ This ctor can be rewritten as:

```
Dog::Dog(char *name, Breed breed, int age)
: m_name(new char[strlen(name)+1]),
  m_breed(breed), m_age(age) {
    strcpy(m_name, name);
}
```

- The constructor might look like this

```
Dog::Dog(char *name, Breed breed, int age) {
    m_name = new char[strlen(name)+1];
    strcpy(m_name, name);
    m_breed = breed;
    m_age = age;
}
```

15

Constant Data Member Initialization

- The breed of the dog will not change, so let us make this a constant variable in the class declaration.

```
class Dog {
public:
    Dog();
    Dog(char *name, Breed breed, int age);
    ~Dog();
    void list() const;
private:
    char *m_name;
    const Breed m_breed;
    int m_age;
};
```

✧ Constant variables **MUST** be initialized in the initialization list
`Dog::Dog():m_breed(undefined) {}`

- Other good uses for const

```
Dog::Dog(const char *name, const Breed breed, const int age)
: m_name(new char[strlen(name)+1]),
  m_breed(breed), m_age(age) {
    strcpy(m_name, name);
}
```

16

Initialization List (cont'd)

- ✧ There are several cases where initialization list **MUST** be used
 - * Constant data member
 - * Reference data member
 - * Non-default parent class constructor
 - * Non-default component object constructor
- ✧ Coding style: use initialization list as much as possible
 - * initialization list is inevitable in many cases
 - * initialization will be performed implicitly in the initialization list whether you use it or not. It saves some computation to do it in the initialization list.
- ✧ Caution:
 - * The order of expressions in the initialization list is NOT the order of execution, the defining order of member variables in the class definition defines the order of execution.

```
Dog::Dog(const char *name, const Breed breed, const int age)
: m_age(age), m_name(new char[strlen(name)+1]), m_breed(breed){
  strcpy(m_name, name);
}
```

Diagram labels: **third** points to `m_name`, **first** points to `m_age`, **second** points to `m_breed`.

17

Ctor of Intrinsic Data Type

- ✧ int, long, float, double, char
- ✧ Initialize with constructor:
`int x(10);`
- ✧ Construction of a temporary variable
`int x;`
`x = int(10.3);` // assignment from a temporary integer
// which is initialized with 10.3
- ✧ Some people think that this is a kind of coercion like
`x = (int) 10.3;`
Actually the above two are not the same mechanism in C++. Each invoke different procedures to achieve their specified functions.

18
