Visual C++ 6.0

Visual C++ 6.0

Visual C++ 6.0

13

Visual C++ 6.0

❖ Compile a single source file

14

Visual C++ 6.0

❖ Build the whole project

15

Visual C++ 6.0

❖ Execute

- ❖ .exe file is located in the "Debug" directory in debug configuration
- ❖ .exe file is located in the "Release" directory in release configuration

16

Visual C++ Command-Line Compiler

✧ Download at:

- ★ <http://msdn.microsoft.com/visualc/vctoolkit2003/>

✧ Install the toolkit

✧ Configure environment:

- ★ Set PATH=<the toolkit directory>\bin;%PATH%
- ★ Set INCLUDE=<the toolkit directory>\include;%INCLUDE%
- ★ Set LIB=<the toolkit directory>\lib;%LIB%

. 17

Visual C++ Command-Line Compiler

✧ Compile and Build

> **cl foo.c**

or

> **cl foo1.c foo2.c -OUT:foo.exe**

✧ Compile

> **cl -c foo.c**

✧ Link

> **link foo1.obj foo2.obj -OUT:foo.exe**

. 19

Basic Programming Concepts

- ✧ Controlling the CPU+Memory+I/O to obtain your computational goals
- ✧ Memory: provides storages for your data
 - ★ Constants: 1, 2, 'A', "a string"
 - ★ Variables: int count;
- ✧ CPU: provides operations to data
 - ★ Data movement: count = 1;
 - ★ Arithmetic or Boolean expressions: 2 * 4
 - ★ Testing and control flow: if statement, for loop, while loop, function
- ✧ I/O: FILE, stdin, stdout, printf(), scanf(), getc(), ... 20

Basic Programming Concepts

Procedural programming basics

- ✧ Step 1: represent your data in terms of variables
 - basic types: char, int, float, double
 - user defined types: struct...link lists, trees,...
 - (Here are what you learned in Data Structure)
- ✧ Step 2: figure out how to transform the original data to the desired data that you want to see with the primitive operations a computer provides: ex. search, sort, arithmetic or logic computations,...
- (Here is what you learned in Algorithm)

21

Contents

- ✧ C Development Environment
- ✧ Basic Procedural Programming Concepts
- ✧ **Functions**
- ✧ Pointers and Arrays
- ✧ Strings
- ✧ Basic I/O
- ✧ Memory Allocation
- ✧ File Operation
- ✧ Reading the Command Line

22

Function Basic

- ✧ A simple function compute the value of val^{pow}

23

Function Definition

- ✧ The first line of the function, contains:
 - * Return data type
 - * Function name
 - * Parameter list, for each Parameter, contains:
 - ✧ Parameter data type
 - ✧ Parameter name

24

Function Body

- ✧ Function Body is bounded by a set of curly brackets
- ✧ Function terminates when:
 - ★ “return” statement is reached or
 - ★ the final closing curly bracket is reached.
- ✧ Function returns value by:
 - ★ “return(ret_val);” statement, the ret_val must be of the same type in function definition;
 - ★ Return automatically when reaching the final closing curly bracket , the return value is meaningless.

• • • • • • • • • • 25

Function Declaration & Function Call

- ✧ Function can be called only after it is declared, a simple skeletal program:

• • • • • • • • • • 26

Function Call

- ✧ Function can be called at any part of the program after the declaration:
 - ★ The return value of a function can be assigned to a variable of the same type.
 - ★ Example: `result = power(2, 5);`
 - ✧ Compute the value of $2^5 = 32$ and assign the value to the variable “result”, equals to “result=32”.

• • • • • • • • • • 27

Function Parameter

- ✧ C is “called by value”
 - ★ The function receives copies of values of the parameters
 - ★ Example:
 - ✧ Print “a=10” and “x=314.159”

• • • • • • • • • • 28

Function Variable Scope

- ✧ Limited in the function
- ✧ Created each time when called
- ✧ Example,
 - ★ pi: whole program
 - ★ result, a: main
 - ★ x,y: circlearea

```
float circlearea(int x);  
float pi=3.14159; ← Global variable  
void main()  
{  
    float result, a=10; ← Local variable  
    result=circlearea(a);  
    printf( "a=%d" ,a);  
}  
float circlearea(int x)  
{  
    float y; ← Local variable  
    y = pi*x*x; x=y;  
    printf( "x=%d" ,x);  
    return y;  
}
```

Contents

- ✧ C Development Environment
- ✧ Basic Procedural Programming Concepts
- ✧ Functions
- ✧ **Pointers and Arrays**
- ✧ Strings
- ✧ Basic I/O
- ✧ Memory Allocation
- ✧ File Operation
- ✧ Reading the Command Line

• • • • • • • • • • 30

Basic Pointer Operations

- ✧ Declaration: with asterisk *.
 - ★ int *ip; (declare a variable of integer address type)
- ✧ Generation: with “address-of” operator &.
 - ★ int i = 5; ip = &i; (ip points to the address of i)
- ✧ Retrieve the value pointed to by a pointer using the “contents-of” (or “dereference”) operator, *.
 - ★ printf("%d\n", *ip); (equals to “printf("%d\n", i);”)
 - ★ *ip=10; (equals to “i=10”)

• • • • • • • • • • 31

Pointers and Arrays

- ✧ Pointers do not have to point to single variables. They can also point at the cells of an array.
 - ★ int *ip; int a[10]; ip = &a[3];
- ✧ An array is actually a pointer to the 0-th element of the array
 - ★ int *ip; int a[10]; ip = a; (equals to “ip = &a[0]”)
 - ★ a[5]=10; is equivalent to *(a+5)=10;
- ✧ Pointers can be manipulated by “+” and “-”.
 - ★ int *ip; int a[10]; ip = &a[3];
 - ★ The pointer “ip-1” points to a[2] and “ip+3” points to a[6];

• • • • • • • • • • 32

Pointers and Arrays: Example

• • • • • • • • • • 33

Additional Information

- ✧ Pointer is a variable too, the content of a pointer is the address of the memory.
 - ✧ Pointers can also form arrays, and there can be a pointer of pointer.
- ```
int * pt[10];
int ** ppt; (viewed as int * * ppt;)
ppt = &pt[0] (or ppt = pt);
```

• • • • • • • • • • 34

- ✧ File Operation
- ✧ Reading the Command Line

• • • • • • • • • • 35

## String basic

- ✧ Strings in C are represented by arrays of characters.
- ✧ The end of the string is marked with the *null character*, which is simply the character with the value 0. (Also denoted as '\0');
- ✧ The string literals:
  - \* char string[] = "Hello, world!";
  - \* we can leave out the dimension of the array, the compiler can compute it for us based on the size of the initializer (including the terminating \0).

Note:

```
char string[]; is illegal
string = "Hello, world!"; is illegal
```

• • • • • • • • • • 36

## String handling

- ✧ Standard library <string.h>
- ✧ For details, please refer to manual: such as MSDN

|                 |                          |
|-----------------|--------------------------|
| strcat, strncat | Append string            |
| strchr, strchr  | Find character in string |
| strcpy, strncpy | Copy string              |
| strcmp, strncmp | Compare string           |
| strlen          | Return string length     |
| strstr          | Find substring           |

- ✧ Strings
- ✧ **Basic I/O**
- ✧ Memory Allocation
- ✧ File Operation
- ✧ Reading the Command Line

. . . . . 39

## Char I/O

- ✧ “getchar”: getchar returns the next character of keyboard input as an int.
- ✧ “putchar”: putchar puts its character argument on the standard output (usually the screen).

```
#include <ctype.h>
/* For definition of toupper */
#include <stdio.h>
/* For definition of getchar, putchar, EOF */
main()
{ int ch;
 while((ch = getchar()) != EOF)
 putchar(toupper(ch));
}
```

. . . . . 40

## String I/O

- ✧ “printf”: Generates output under the control of a *format string*
- ✧ “scanf”: Allows *formatted reading* of data from the keyboard.

. . . . . 41

## Format Specification

- ✧ Basic *format specifiers* for printf and scanf:
  - ★ %d print an int argument in decimal
  - ★ %ld print a long int argument in decimal
  - ★ %c print a character
  - ★ %s print a string
  - ★ %f print a float or double argument
  - ★ %o print an int argument in octal (base 8)
  - ★ %x print an int argument in hexadecimal (base 16)

- ✧ File Operation
- ✧ Reading the Command Line

. . . . . 43

## Allocating Memory with “malloc”

- ✧ Is declared in <stdlib.h>
  - ★ void \*malloc( size\_t size );
- ✧ Returns a pointer to *n* bytes of memory
  - ★ *char \*line = (char \*)malloc(100);*
- ✧ Can be of any type;
  - ★ Assume “date” is a complex structure;
  - ★ *struct date \*today = (struct date \*)malloc(sizeof(struct date));*
- ✧ Return null if failed

. . . . . 44

## Freeing Memory

- ✧ Memory allocated with *malloc* lasts as long as you want it to.
- ✧ It does not automatically disappear when a function returns, but remain for the entire duration of your program.
- ✧ Dynamically allocated memory is deallocated with the *free* function.
  - ★ *free(line); free(today);*
  - ★ fail if the pointer is null or invalid value

. . . . . 45

## Reallocating Memory Blocks

- ✧ Reallocate memory to a pointer which has been allocated memory before (maybe by *malloc*)
  - ★ *void \*realloc( void \*memblock, size\_t size );*
  - ★ *today\_and\_tomorrow = realloc(today, 2\*sizeof(date));*

. . . . . 46

- ✧ Strings
- ✧ Basic I/O
- ✧ Memory Allocation
- ✧ **File Operation**
- ✧ Reading the Command Line

. . . . . 47

## File Pointers

- ✧ C communicates with files using a extended data type called a file pointer.
  - ★ *FILE \*output\_file;*
- ✧ Common file descriptors:
  - ★ “stdin”: The standard input. The keyboard or a redirected input file.
  - ★ “stdout”: The standard output. The screen or a redirected output file.
  - ★ “stderr”: The standard error. The screen or a redirected output file.

. . . . . 48

## Open and Close

- ✧ Using *fopen* function, which opens a file (if exist) and returned a file pointer
  - ★ `fopen("output_file", "w");`
- ✧ Using *fclose* function, which disconnect a file pointer from a file
- ✧ Access character:
  - ★ “r”: open for reading;
  - ★ “w”: open for writing;
  - ★ “a”: open for appending.

. . . . . 49

## File I/O

- ✧ Standard library `<stdio.h>`
- ✧ For details, please refer to manual: such as MSDN

|                            |                                    |
|----------------------------|------------------------------------|
| <code>putchar, putc</code> | Put a character to a file          |
| <code>getchar,getc</code>  | Get a character from a file        |
| <code>fprintf</code>       | Put formatted string into a file.  |
| <code>fscanf</code>        | Take data from a string of a file. |
| <code>fputs</code>         | Put a string into a file           |
| <code>fgets</code>         | Get a string from a file           |

. . . . . 50

## Contents

- ✧ Pointers and Arrays
- ✧ Strings
- ✧ Basic I/O
- ✧ Memory Allocation
- ✧ File Operation
- ✧ **Reading the Command Line**

. . . . . 51

## Reading the Command Line

- ✧ C's model of the command line of a sequence of words, typically separated by whitespace.
- ✧ A program with command arguments:
  - ★ `int main(int argc, char *argv[]) { ... }`
  - ★ “argc” is a count of the number of command-line arguments.
  - ★ “argv” is an array (“vector”) of the arguments themselves.

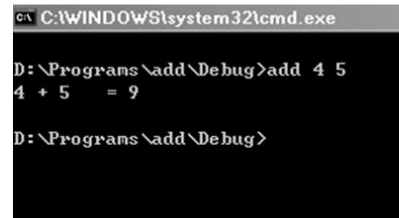

Ex.

sort file1 file2 file3

. . . . . 52

# Example

```
#include <stdio.h>
#include <stdlib.h>
main(int argc, char *argv[])
{
 int a = atoi(argv[1]);
 int b = atoi(argv[2]);
 int sum = a + b;
 printf("%s + %s = %d\n", argv[1], argv[2], sum);
}
```

The screenshot shows a Windows command prompt window with the title bar "C:\WINDOWS\system32\cmd.exe". The prompt is "D:\Programs\add\Debug>". The user has entered the command "add 4 5". The output of the program is displayed as "4 + 5 = 9". The prompt is now "D:\Programs\add\Debug>" again, ready for the next command.

argc = 3  
argv[0] = "add"  
argv[1] = "4"  
argv[2] = "5"
