

Chapter 2.

Making And Using Objects

C++ Object Oriented Programming
Pei-yih Ting
93/02 NTOU CS

• • • • • • • 1

Content

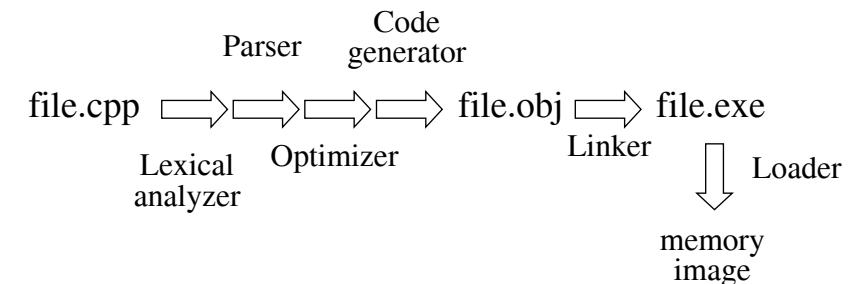

- ✧ Program compilation and linking
- ✧ Type checking system
- ✧ Separate compilation
- ✧ Declaration vs. Definition
- ✧ #include preprocessor directive
- ✧ Using libraries
- ✧ Namespace
- ✧ Using iostream and iomanip
- ✧ String class
- ✧ File I/O with fstream
- ✧ Container: vector

2

Interpreter vs. Compiler

- ✧ Interpreter
 - * translate each source code executed into **machine activities**
 - * retranslate each line executed, skip those not encountered
 - * Pros: rapid development(modification/debugging/interaction), easy to automate
 - * Cons: slow for computation intensive jobs
 - * BASIC, PERL
- ✧ Compiler
 - * Translate source codes into **machine instructions**
 - * Translate the whole program only once
 - * Slow development cycle as a tradeoff to fast execution
- ✧ Combination
 - * Python, JAVA: have intermediate language, platform indep.

C++ Compilation/Linking/Execution

3

4

C++ Compilation/Linking/Execution

- ❖ Preprocessor: process #preprocessor directives

ex.

```
#define PI 3.14159
#ifndef _WIN32
#define SQUARE(x) ((x)*(x))
#pragma warning (disable:4768)
#include <iostream>
```

- Save typing
- Increase readability
- Parser does not see them
- Debugger does not see them
- **Introduce subtle bugs**

- ❖ Lexical analyzer: breaks the source code into small units

- ❖ Syntactical parser: organizes into a parse tree according to the grammar

- ❖ Optimizer: produces smaller or faster code

- ❖ Code generator: generate object(target) machine code (*.obj) according to the parse tree

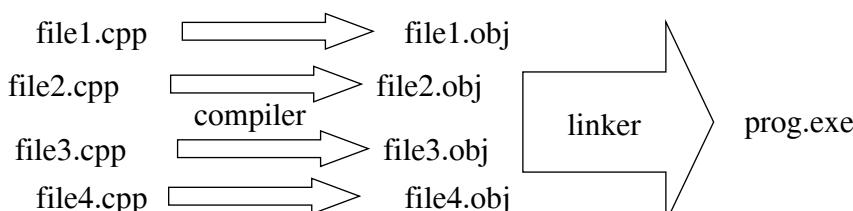

- ❖ Linker: resolves variables or routines references outside each independent object module, produce a relocatable execution code

- ❖ Loader: loads the executable from file into the memory

5

Separate Compilation

- ❖ Each module is put in a separate file, which is a small, manageable, independently tested piece
- ❖ Editing of one module does not involve other module: avoid editing mistakes
- ❖ Compilation of one module only checks the grammar syntax and does not involve other modules: large project can proceed independently, better encapsulation
- ❖ C/C++ compiler provides the functionality of separate compilation

7

Type Checking

- ❖ Static Type Checking: ensure that each grammatical objects have the correct type by the parser and enforce type conversion, ex. proper data types of function arguments

- ★ Weak type checking: Perl

- ★ Strong type checking: C/C++, PASCAL

In C/C++ you can disable type checking by **coercion**.

- ❖ Dynamic type Checking: perform type checking at runtime, more powerful but adds overhead to program execution

- ★ Java

- ★ C++ RTTI (run time type information)

- ★ MFC Runtime class

6

Declaration vs. Definition

- ❖ Function: the atomic unit of code in C/C++

- ★ must be put in a single file

- ★ has a name, some parameters and a return value.

- ❖ Each file contains **definitions** of:

- ★ Data: the type of that identifier and allocates memory

- ★ Function: the name, the parameters, the return values and the codes

- ❖ To access a function (to call a function) or a variable defined in another file

- ★ you must **declare** the function or the variable first in that file, so the compiler knows what the identifier represents, can perform the type checking, and can deal with it (conversion)

- ★ Ex. declarations:

```
int func1(int, float, char *);  
extern int x;
```

You can declare an identifier
many times but you can only
define it once.

8

Declaration vs. Definition

- ❖ Declare.cpp // Declaration & definition examples page84

```
extern int i; // Declaration without definition  
extern float f(float); // Function declaration
```

```
float b; // Declaration & definition  
float f(float a) { // Definition  
    return a + 1.0;  
}
```

```
int i; // Definition  
int h(int x) { // Declaration & definition  
    return x + 1;  
}
```

```
int main() {  
    b = 1.0;  
    i = 2;  
    f(b);  
    h(i);  
}
```

9

#include preprocessor directive

- ❖ #include <stdio.h>
 #include <stdlib.h>

```
#include <cstdio>  
#include <cstdlib>
```

- ❖ Where are those functions defined in the include files?

- * Their object codes are in the library: ex. libc.lib
use lib tool to view the contents of *.lib files
- * All C/C++ compilers direct the linker to search the standard library automatically

11

#include preprocessor directive

- ❖ Insert the contents of the specified file in the place of your #include statement for the following compilation

- * #include <header.h>

search the current directory and the specified directories in the 'include search path'

- * #include "header.h"

search the current directory for the header file

- ❖ To see what is included:

- * Compiler options: using VC as example: cl /E or cl /P

* View the included file in the system directory: ex.
C:\Program Files\Microsoft\VC98\include

- ❖ C++ convention

- * #include <iostream.h> old versions

- * #include <iostream> new template versions
using namespace std;

10

Using Libraries

- ❖ Libraries contains one or many object modules

- ❖ To use a library:

- * Include the header file of an object file in a library
- * Use the functions and variables in the object module of a library
- * Link the library into the executable program

- ❖ How the linker searches a library

- * It searches the 'unresolved references' one library by one library
- * If there are many repeated definitions of a certain function, the first library containing the definition is used.
 - * The order of libraries supplied to the linker is crucial
 - * You can preempt the use of a library function by inserting a version of yours
- * Once an unresolved reference is located in an object module of a library, the object module is extracted out of that library and combined to the executable.

12

Using Libraries (cont'd)

- ❖ How do the following two usages differ?

- * First scenario:

```
cl /Femain.exe main.c tool1.c tool2.c tool3.c tool4.c tool5.c
```

- * Second scenario:

```
cl /c /Fotool1.obj tool1.c
```

```
cl /c /Fotool2.obj tool2.c
```

```
cl /c /Fotool3.obj tool3.c
```

```
cl /c /Fotool4.obj tool4.c
```

```
cl /c /Fotool5.obj tool5.c
```

```
lib /out:tool.lib tool1.obj tool2.obj tool3.obj tool4.obj tool5.obj
```

```
cl /Femain.exe main.c tool.lib
```

13

Namespace: avoid name collisions

- ❖ Namespace definition

```
namespace Foo {  
    int var;  
    int foofun(int x) {  
        return x;  
    }  
}
```

- ❖ using directive

```
int main() {  
    using namespace Foo;  
    int testvar;  
    return foofun(testvar+Test::testvar+  
        var+Foo::var);  
}
```

- ❖ using declaration

```
using Foo::foofun;  
foofun(10);
```

```
namespace Test {  
    int testvar;  
    int testfun(int x) {  
        return x;  
    }  
}  
....  
namespace Test {  
    int anotherVar;  
    int anotherFun();  
}  
...  
int Test::anotherFun() {  
    return 1;  
}
```

14

Namespace (cont'd)

- ❖ Definition rules:

1. you can use whatever identifiers as long as it does not occur twice at the same level of the same namespace. The "using namespace" statement has no effect on the definition of identifiers.
2. identifiers can have the same name in different namespaces

- ❖ Usage rules:

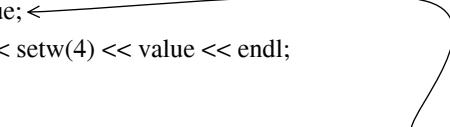

1. "using namespace" statement set up a list of backup namespaces for the compiler to resolve an identifier. There can be ambiguous definitions in these namespaces as long as you specify them explicitly.
2. When resolving an identifier, the compiler starts from the default namespace. If the identifier is defined, no search in the backup namespaces will be conducted; if it is not found in the default namespace, the compiler searches ALL backup namespaces defined by "using namespace" for the specified identifier. If this identifier occurs several times in these namespaces, the compiler complains for ambiguity about the usage of this identifier.

15

Using iostream and iomanip

- ❖ C++ standard input/output modules

```
#include <iostream>  
#include <iomanip>  
using namespace std;
```

```
void main() {  
    int value;  
    cout << "Howdy!" << endl;  
    cout << "Please input an integer ";  
    cin >> value;   
    std::cout << setw(4) << value << endl;  
}
```

 Note: the difference with scanf("%d", &value);

16

Miscellaneous

- ❖ Calling other programs: system()

```
#include <cstdlib>
using namespace std;
int main() {
    system("hello.exe"); // executes hello.exe and returns to the program
}
```

- ❖ _FILE_, _LINE_, _DATE_, _TIME_:

compiling file, line #, date, and time as string into the program

- ❖ cout << _FILE_ << " " << _DATE_ << _TIME_ << endl;
- ❖ assert() macro's output

- ❖ ctime(), time.h: getting the system time

17

Standard C++ *string* class

- ❖ Properties:(more abstract and convenient character array implementation)

- ❖ Dynamic memory management
 - ❖ Character array copying
 - ❖ Concatenation

- ❖ Header file: #include <string>

- ❖ Namespace: using namespace std;

- ❖ Ex.

```
string s1, s2;                                // empty strings
string s3 = "Hello, World.";                     // initialized
string s4("I am");                            // initialized
char dest[100];
s2 = "today";                                 // string copy
s1 = s3 + " " + s4;                           // concatenation of strings
s1 += " 8 ";                                  // appending to a sting
cout << s1 + s2 + "!" << endl;                // extended ostream
strcpy(dest, s1.c_str());                      // convert to char array
cin >> s1;
cout << s1.length();                          // or s1.size();
if (s3 + s4 == "Hello, World.I am") ...
```

18

Reading/writing files with *fstream*

- ❖ Avoid the complexity of C's file operations

- ❖ Header file: #include <fstream>

- ❖ Namespace: using namespace std;

- ❖ Ex.

explicit open not required

```
ifstream in("Scopy.cpp"); // open for reading
ofstream out("Scopy2.cpp"); // open for writing
string s;
while (getline(in, s)) // delimiter '\n' deleted automatically
    out << s << "\n";
```

- ❖ getline() returns false upon reaching the end of the input and the returned string become empty

19

fstream cont'd

- ❖ Ex.

```
ifstream in("FillString.cpp"); // open for reading
string s, line;
while (getline(in, line)) s += line + "\n";
cout << s;
```

* Exercises:

- ❖ Concatenate 2 files with filename headers
- ❖ Add line # to each line in a file
- ❖ Search a specific string and print out with line #

line.find("hello");

- ❖ The delimiter of getline() function can be changed

- ❖ Ex. getline(in, s, ';');

20

Standard C++ *vector* class

- ✧ Container object:
 - * hold any kind of object
 - * dynamically adjust its memory size
- ✧ Vector class is a template: can be efficiently applied to different types ex. vector of strings, vector of integers...
- ✧ Declaration: `vector<string> obj;`
- ✧ Header file: `#include <vector>`
- ✧ Namespace: `using namespace std;`
- ✧ Interfaces:
 - * `push_back()`
 - * `insert()`
 - * `size()`
 - * indexing: `a[4]` like an array

21

vector

```
1. // cl -GX Fillvector.cpp
2. // copy an entire file into a vector of strings
3. #include <iostream>
4. #include <iostream>
5. #include <vector>
6. #include <string>
7. using namespace std;
8. int main() {
9.     ifstream inf("Fillvector.cpp");
10.    string line;
11.    vector<string> lines;
12.    while (getline(inf, line))
13.        lines.push_back(line); // add the line to the end
14.    cout << lines.size() << endl;
15.    for (int i=0; i<lines.size(); i++)
16.        cout << i << ":" << lines[i] << endl;
17.    return 0;
18. }
```

The object *line* is copied into *lines* and the main program can destroy the *line* object afterwards.

The container object *lines* is going to handle all memories at the destruction.

22

Summary

- ✧ OOP:
 - * Programming based on objects, to be more exact, based on the interface of objects
 - * Suitable encapsulation hides the detailed implementations of an object and exhibits only the interface of a certain simple abstract model
 - * Usages of an object:
 - * Include a header file
 - * Create the objects
 - * Send messages to them
 - * Get their responses

23
